REQUIREMENT ANALYSIS

Project Title

Implement Client Script & UI Policy in Service Now Incident

1. Introduction

Requirement Analysis is an important stage in the development of any project. It identifies what the system should do, what users need, what resources are required, and what conditions must be satisfied before implementation. In this project, the requirement analysis focuses on implementing Client Scripts and UI Policies on the Service Now Incident form.

The main purpose of this phase is to convert the idea identified during the Brainstorming and Ideation Phase into clear and measurable requirements. The requirements describe the expected behavior of the Incident form and provide a foundation for project design and development.

The project requires the Incident form to respond appropriately when users enter or change information. Certain fields may need to become mandatory, visible, or read-only depending on conditions. Client Scripts can provide JavaScript-based client-side logic, while UI Policies can control field behavior through configuration.

This phase therefore identifies functional requirements, non-functional requirements, user requirements, technical requirements, software requirements, hardware requirements, input requirements, output requirements, and project constraints.

2. Purpose of Requirement Analysis

The purpose of requirement analysis is to clearly define the expected functionality before development begins. It prevents confusion during implementation and helps ensure that the final project meets the intended objectives.

- Identify the functions required in the Incident form.
- Define the expected behavior of Client Scripts.
- Define the expected behavior of UI Policies.
- Identify the users who will interact with the project.
- Identify the ServiceNow resources required for implementation.
- Define testing requirements for the configured behavior.
- Provide a clear foundation for project design and development.

3. Requirement Identification

The requirements were identified by examining the expected workflow of an Incident record. The project should allow a user to open an Incident form, enter relevant information, change selected field values, and receive appropriate dynamic behavior. The system should also help ensure that required information is available before the Incident is submitted or moved through important states.

4. Stakeholders

The main stakeholders associated with the project are the ServiceNow users, IT support staff, ServiceNow administrators, and developers. Each stakeholder has a different role in the Incident process.

- Service Desk User – creates and updates Incident records.
- IT Support Engineer – investigates and resolves Incidents.
- ServiceNow Administrator – configures UI Policies and manages platform settings.
- ServiceNow Developer – creates and maintains Client Scripts and other custom logic.
- Project Team – implements, tests, documents, and demonstrates the solution.

5. Functional Requirements

Functional requirements describe the specific actions and behavior that the project should provide. These requirements define what the system must do when a user interacts with the Incident form.

ID	Requirement	Description
FR-01	Incident Form Access	The user should be able to open and work with the ServiceNow Incident form.
FR-02	Field Input	The user should be able to enter appropriate Incident information in the available fields.
FR-03	UI Policy Condition	The system should evaluate the condition configured in the UI Policy.
FR-04	Mandatory Control	Selected fields should become mandatory when the configured condition is satisfied.
FR-05	Visibility Control	Selected fields should be shown or hidden according to the configured condition.
FR-06	Read-only Control	Selected fields should become read-only when required by the project rule.
FR-07	Client Script Execution	The Client Script should execute according to its configured type and trigger.
FR-08	OnChange Behavior	An onChange Client Script should respond when the selected field value changes.

FR-09	Validation	The system should provide appropriate client-side validation for the selected requirement.
FR-10	Record Submission	The user should be able to submit the Incident after required information is provided.

6. Non-Functional Requirements

Non-functional requirements describe the quality and operational expectations of the project rather than individual functions.

- Usability – The Incident form should be simple and understandable for users.
- Performance – Client-side actions should execute without unnecessary delay.
- Reliability – Configured rules should behave consistently under the defined conditions.
- Maintainability – Client Scripts and UI Policies should be organized so they can be understood and maintained.
- Accuracy – The system should apply the intended field behavior correctly.
- Compatibility – The implementation should work within the selected ServiceNow environment.
- Security – Only authorized ServiceNow users should access and modify Incident records according to their roles and permissions.

7. User Requirements

Users require an Incident form that provides clear guidance while they create or update records. The system should reduce unnecessary manual decisions and help users provide important information at the appropriate stage.

- Users should understand which fields are required.
- Users should receive appropriate dynamic field behavior.
- Users should be able to complete the Incident without unnecessary fields creating confusion.
- Users should be able to enter resolution information when the Incident reaches the appropriate state.

8. Technical Requirements

The project requires a ServiceNow environment in which the Incident table, Client Scripts, and UI Policies can be configured. The development team must have sufficient access to create and test the required configurations.

- ServiceNow instance with access to Incident Management.
- Access to the Incident [incident] table.
- Permission to create or configure Client Scripts.
- Permission to create or configure UI Policies.
- JavaScript knowledge for Client Script development.
- A supported web browser for accessing the ServiceNow instance.
- Test Incident records for validating the implementation.

9. Software Requirements

Software / Platform	Purpose
ServiceNow	Main platform for Incident Management and project implementation.
Web Browser	Accesses the ServiceNow web interface.
JavaScript	Used for Client Script logic.
Documentation Tool	Used to prepare project reports and documentation.

10. Hardware Requirements

The project does not require specialized hardware. A normal computer or laptop with internet connectivity is sufficient for accessing the ServiceNow environment.

- Laptop or desktop computer.
- Stable internet connection.
- Keyboard and mouse.
- Sufficient system memory to run a modern web browser.
- Screen recording capability for the final demonstration video.

11. Input Requirements

The project receives information through the Incident form. The user may provide details such as Incident description, selected state, priority-related information, and other fields available in the configured form.

- Incident information entered by the user.
- Values selected from Incident fields.
- Changes made to selected fields.
- Incident state changes.
- Information required for resolution.

12. Output Requirements

The expected output is the dynamic behavior of the Incident form. Based on the configured conditions, the system should change selected fields and provide the expected validation behavior.

- Fields becoming mandatory when required.
- Fields becoming visible or hidden according to conditions.
- Fields becoming read-only where required.
- Client-side validation when configured.
- Successful Incident submission after required information is supplied.

13. Client Script Requirements

The project requires at least one suitable Client Script to demonstrate client-side behavior. The script should be configured for the Incident table and should have a clearly defined trigger and purpose.

- The Client Script should be associated with the Incident table.
- The script should use appropriate JavaScript syntax.
- The script should have a clearly defined execution type such as onChange where applicable.
- The script should check the relevant condition before applying an action.
- The script should avoid unnecessary execution when the form is loading, where appropriate.
- The script should produce the expected field behavior during testing.

14. UI Policy Requirements

The project requires a UI Policy that controls Incident fields based on a defined condition. The policy should be configured with the Incident table and appropriate UI Policy Actions.

- The UI Policy should be associated with the Incident table.
- A clear condition should be defined.
- UI Policy Actions should identify the fields to be controlled.
- The mandatory, visible, or read-only behavior should be configured according to the requirement.
- The policy should be tested in both condition-true and condition-false situations.

15. Business Rules / Conditions Considered

The project is primarily focused on Client Scripts and UI Policies. During requirement analysis, the team should clearly distinguish client-side requirements from server-side requirements. The selected rules in this project are intended to operate on the Incident form and respond to user interaction.

A key example is the Incident state. When the state reaches Resolved, the project can require resolution information. The exact fields and conditions should be finalized during the design phase and then implemented and tested during development.

16. Requirement Traceability

Requirement	Implementation	Testing
Mandatory fields	UI Policy / Client Script	Verify field becomes mandatory
Dynamic visibility	UI Policy	Verify field visibility changes
Read-only behavior	UI Policy / Client Script	Verify field cannot be edited when required
Client-side validation	Client Script	Enter test values and observe behavior
Incident state condition	UI Policy condition	Test condition true and false

17. Constraints and Assumptions

- The project assumes that a working ServiceNow development or training instance is available.
- The project depends on appropriate user permissions.
- The project is focused on the Incident form and selected client-side behavior.
- Internet connectivity is required to access the ServiceNow instance.
- The final configuration may vary depending on the available ServiceNow instance and its existing configuration.

18. Acceptance Criteria

The project will be considered ready for the next phase when the required Client Script and UI Policy behavior is clearly defined, the Incident form requirements are documented, and the team has identified the conditions, fields, tools, and tests needed for implementation.

19. Conclusion

The Requirement Analysis Phase converts the initial project idea into a structured set of functional, non-functional, technical, user, input, output, and testing requirements. The analysis establishes that the ServiceNow Incident form should provide dynamic field behavior through Client Scripts and UI Policies. These requirements will be used as the foundation for the Project Design Phase, where the system structure, workflow, field behavior, and implementation design will be prepared.
