Requirement Analysis

Project Title

Implement Client Script & UI Policy (Incident)

1. Introduction

The Requirement Analysis phase identifies the requirements needed to implement the Client Scripts and UI Policy for ServiceNow Incident records. The main purpose is to ensure that Incident records contain complete and valid information and that specific fields behave according to the defined conditions.

2. Functional Requirements

The system should provide the following functions:

2.1 High Impact UI Policy

A UI Policy named High Impact Control should be created on the Incident table.

Condition:

- Field: Impact
- Operator: is
- Value: 1 – High

When this condition is satisfied, the configured UI Policy actions should be applied.

2.2 Urgency Field Control

When Impact is High:

- The Urgency field should become read-only.
- The field should remain visible.
- The behavior should be controlled through a UI Policy Action.

2.3 Automatic Urgency Update

An onChange Client Script should monitor the Impact field.

When Impact is changed to High, the script should automatically set Urgency to High and display an information message.

2.4 Assigned To Validation

An onSubmit Client Script should validate the Assigned To field.

If Impact is High and Assigned To is empty:

- The Incident should not be saved.
- An error message should be displayed.
- The user should be required to provide Assigned To.

2.5 State List-Edit Restriction

An onCellEdit Client Script should control State changes made directly from the Incident list.

When a user attempts to edit State through list editing:

- An alert should be displayed.
- The change should be blocked.
- The user should be instructed to open the Incident form.

3. Non-Functional Requirements

The project should provide:

- Accuracy – Incident information should be consistent.
- Usability – Field behavior should be clear to users.
- Reliability – Validation rules should work consistently.
- Maintainability – Scripts and UI Policies should be easy to understand and manage.
- Efficiency – Client-side controls should provide immediate feedback.

4. Technical Requirements

The project requires:

- ServiceNow instance
- Administrative/configuration access
- Incident table
- UI Policy
- UI Policy Actions
- Client Scripts
- JavaScript
- Incident records for testing

The project specifically uses UI Policy, UI Policy Actions, Client Scripts, Incident Management, and Form Validation.

5. User Requirements

The user should be able to:

1. Create and update Incident records.
2. Select Impact values.
3. View automatic changes to Urgency.
4. Provide Assigned To when required.
5. Receive validation messages when required information is missing.
6. Update State through the Incident form.
7. Understand when list-based State editing is restricted.

6. Validation Requirements

The implementation should be tested to confirm that:

- High Impact makes the configured fields behave correctly.
- Urgency is automatically set to High.
- Missing Assigned To prevents saving.
- A properly completed Incident can be saved.
- Changing Impact from High to Medium reverses the applicable UI Policy behavior.
- Direct State list editing is blocked.
- State changes through the Incident form are allowed.

7. Expected Requirements Outcome

After satisfying these requirements, the ServiceNow Incident form should enforce the defined business rules automatically and provide appropriate validation and field controls.

8. Conclusion

The Requirement Analysis phase defines the functional, technical, user, and validation requirements for the project. The identified requirements provide a clear foundation for designing the UI Policy and Client Scripts in the next phase, Project Design.
